## Tuner Heat Reduction in Standby

Signal processing apparatus, such as the ATC-311 color television receiver chassis produced by Thomson of Indianapolis, Indiana, typically include signal processing circuitry that may be configured in the form of a module. An example of such a module is a module referred to herein as the DM2 that is also produced by Thomson. Such a module typically includes various components and may also include a tuner for selecting a particular signal or channel from a plurality of signals or channels received by the apparatus. A module such as the DM2 may process signals digitally and do so at high data rates. One potential result of high-speed signal processing is that temperature rise of components used in the DM2 may approach or exceed reliability limits.

In addition, signal processing apparatus may have various modes of operation. For example, a color television receiver may be completely disconnected from a power source (power plug disconnected), the receiver may have a "standby" mode of operation (connected to a power source and capable of receiving and processing remote control commands (such as an "on" command) but not operational for producing audio or video output signals), and an "on" or "run" mode of operation (system is fully operational). During certain modes of operation, e.g., "standby" mode, certain system components may be disabled, e.g., to reduce power consumption and noise. In particular, components such as a cooling fan intended to minimize excessive temperature rise of components may be disabled. As a result, component heating in a module such as the DM2 may be exacerbated during a mode of operation such as "standby" mode.

A system described herein solves the described problem by reducing or turning off power supplied to the tuner, e.g., "main" power supply; during one or more modes of operation of the system, e.g., a "standby" mode of operation, thereby reducing heat generation and extending the overall life of the product. As a specific example, by disconnecting the main power supplies to the tuner, internal self-heating of the tuner and subsequent heating of the DM2 module is reduced during the standby mode.

PU020491

An exemplary embodiment of the described system is shown in the Figure. In the Figure, in order to turn OFP the main power supplies to the tuner, a control signal (TUN1\_CNTL) is provided. The state of this control signal is determined by the main CPU, which has sufficient information from various inputs (e.g., a "power off" signal received from a remote control not shown in the Figure) to know when the module should be put into standby. To reduce unnecessary heat generation in the standby mode, two FET transistor switches are used to disconnect the +5V and +12V supplies from the tuner. The control signal goes high in the standby mode and turns 'ON' a NPN transistor (Q24308), this transistor then causes a PNP transistor (Q24307) to turn ON. When the PNP transistor turns ON, it applies the correct gate bias voltage to the FET transistors (U24304) for them to turn 'ON and have low resistance. Low cost N-channel FET transistors can be used because of the availability of the +33V supply to the tuner. Through a resistive divider network (R24339, R24337 and R24335), the appropriate drive voltages to the two different FET transistor switches can be set-up. By the use of this divider network, the voltage applied to each of the gates is correct for the power supply to be switched and not overdrive the gate to source voltage. By the use of these two FET transistor switches, 96 % of the tuner power dissipated is removed in the standby mode. FET switches are used over bipolar switches in order to minimize the amount of power required to turn the tuner 'ON or OFF.

Another embodiment of the described system involves a device, such as a color television receiver or video signal processing apparatus, that includes capability for simultaneously processing both first and second video signals and for processing auxiliary information. As an example, some video signal processing systems receive and process a first video signal to produce a first output signal representing a first, or "main", image and receive and process a second video signal to produce a second output signal representing a second or auxiliary image. The first and second output signals may be coupled to a display device to produce a displayed image including both the main image and the auxiliary image. A specific example of such systems is a picture-in-picture (PIP) or picture-outside-picture (POP) television system. Such systems may, for example, include

PU020491

first and second tuners for simultaneously and independently selecting the respective first and second video signals that will be processed to produce the respective first and second image-representative output signals. In such systems, e.g., a color television receiver with PIP capability, it may also be desirable to provide for receiving and processing auxiliary information. For example, in addition to receiving video and audio signals associated with television programming, it may also be desirable to receive auxiliary information such as Gemstar data, that can be processed to produce an on-screen-display (OSD) such as an electronic program guide (EPG) to simplify and facilitate user interaction with the television receiver. In such systems, it may be desirable to include an additional circuit similar or identical to that described above and shown in the Figure to control the second tuner, e.g., PIP-image signal tuner. In addition to providing a picture in picture display on the TV screen, in a system such as the ATC-311 produced by Thomson, the PIP tuner, when the TV is in standby mode, may be used for Gemstar data collection. To receive and process auxiliary information such as Gemstar data, the tuner must receive power and be operational so that the channel or signal carrying the data can be selected and provided to the signal processing circuitry. To provide the capability to receive and process auxiliary information while also solving the abovedescribed component heating problem, the system provides for turning a tuner on for a particular time period during standby mode, i.e., an interval or portion of the standby period, during which the auxiliary information can be collected and processed. For example, a control device such as a microprocessor included in the system responds to activation of a particular mode of operation such as standby mode by activating a process for controlling power to the tuner. The process includes turning the tuner, e.g., the PIP tune, on for a particular amount of time to collect data and then turn the PIP tuner off (e.g., the duty cycle may be around 30%). The time period or frequency of the power-on data-collection intervals may be varied in response to various factors. For example, the tuner on-time may be varied in response to component temperature (on for longer periods as long as temperature is within acceptable limits). Tuner on-time might also be varied in response to the amount of data to be collected or the data rate, i.e., increase on-time if more data must be received and processed or if a slower data rate requires more processing time, as long as component temperatures are acceptable.
